ABSTRACT:

The two raising elements (1) with a platform include auxiliary elevator plates (5) making it possible to raise the bodywork alone in order to make the wheels free. Moreover, in addition to movable plates (8) provided at the front of the two raising elements (1) of this platform for receiving the front wheels for the purpose of checking their play there is provided, at the rear of these same elements (1), plates (14) for receiving the rear wheels. These plates are mounted so that they can move in the transverse direction and can be moved in this direction by means of actuating cylinders (17) in order to allow the transverse play of the rear wheels to be detected.

This elevator platform may be used for carrying out all the operations necessary for detecting possible play in the wheels of a vehicle, at one single point. <IMAGE>
